Improving the capacity and durability of electrocatalytic systems is one of the most important challenges in electrocatalysis. Several promising approaches have been proposed, but the commonly used graphic-nitrogen-doped carbon (GN) catalysts suffer from low activity and poor stability. In this work, we present a strategy to achieve high activity and stability by using a wide-pore GN as a support. We show that at a concentration of 20 wt% GN, the activity and stability of the catalysts are significantly improved. This work is part of a research project supported by the National Science Foundation (NSF) under Grant No. CBET-0830000.
